Cognitive Media Processing #7

Nobuaki Minematsu

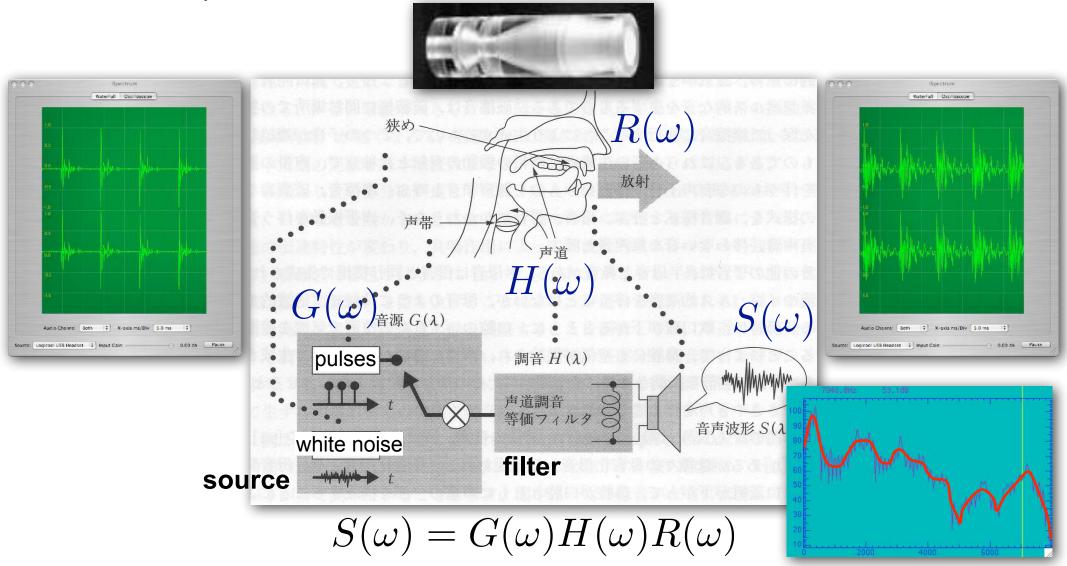

Modeling of speech production

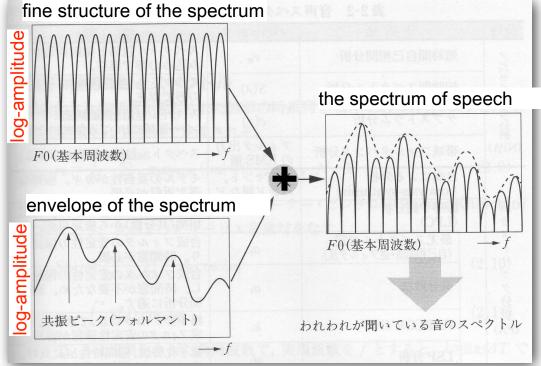

Mathematical modeling of speech production -- source & filter model --

Linear independence between source and filter

Modeling of vowel production

- Mathematical modeling of speech production -- source & filter model --
 - Separation between the spectrums of source and filter

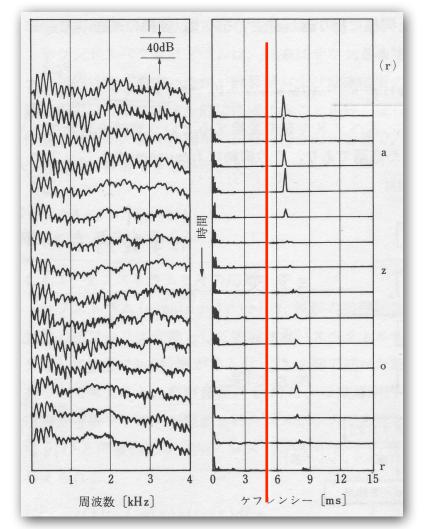

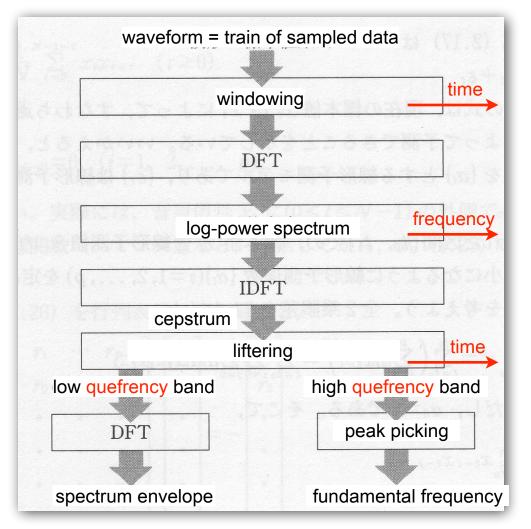

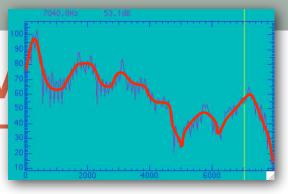

Extraction of spectrum env

- Cepstrum method
 - Windowing + FFT + log-amplitude --> a spectrum with pitch harmonics
 - Smoothing (LPF) of the fine spectrum into its smoothed version

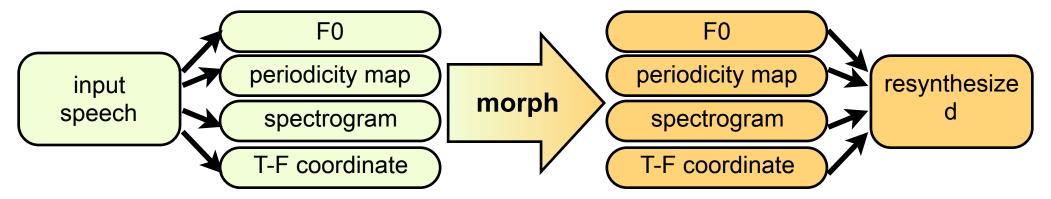

Advanced technology for analysis

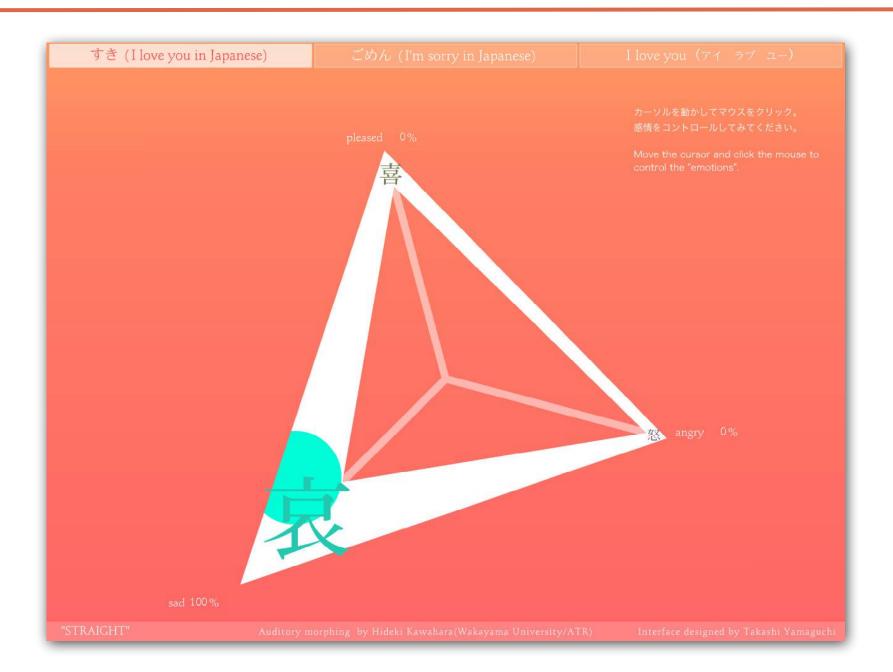

- STRAIGHT [Kawahara'06]
 - High-quality analysis-resynthesis tool
 - Decomposition of speech into
 - Fundamental frequency, spectrographic representations of power, and that of periodicity
 - High-quality speech morphing tool

- Spectrographic representation of power
 - F0 adaptive complementary set of windows and spline based optimal smoothing
- Instantaneous frequency based F0 extraction
 - With correlation-based F0 extraction integrated
- Spectrographic representation of periodicity
 - Harmonic analysis based method

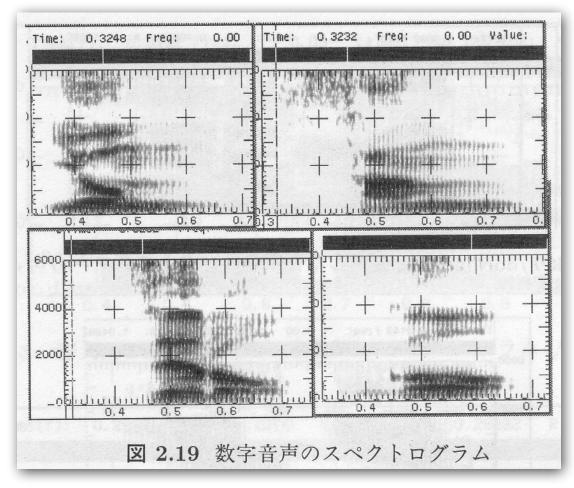

Cognitive Media Processing @ 2015

Examples of speech morphing

Spectrum reading

- What are these?
 - Hint : they are numbers.

• This is the task that is done by a speech recognizer.

Cognitive Media Processing @ 2015

Waveforms --> spectrums --> sequence of feature vectors

Difficulty of ASR

- Task of Automatic Speech Recognition (ASR)
 - Automatic identification of what is said by any speaker
 - Input: spectrum (feature vector) sequence
 - Output: word sequence

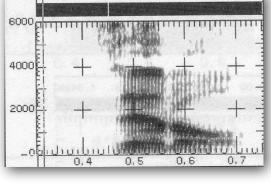

- Factors of the diversity: speaker identity, age, gender, speaking style, channel, line, etc.
- Not explicitly represented in the written form of language.

Linguistic difficulty of ASR

- We're not speaking like the written form of language.
 - How to characterize word sequences in naturally and spontaneously generated speech?
 - How to treat ungrammatical utterances, word fragments, filled pauses, etc?
- Machines do not understand the content of what is spoken.

A well-known strategy for diversity

Statistical framework of ASR

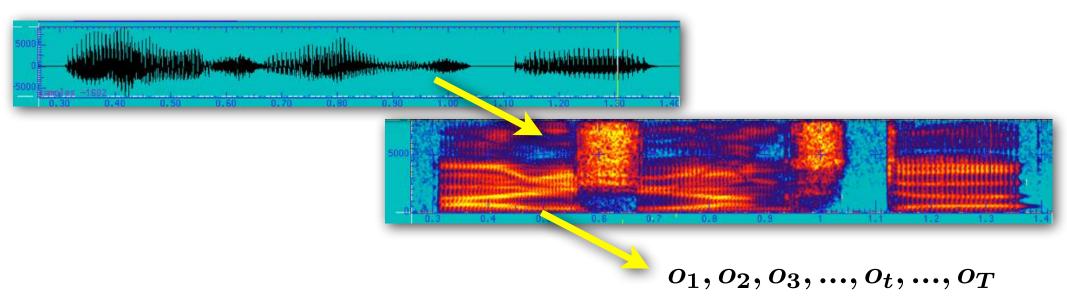

- Solution of argmax_{w} P(w|o)
 - P(w): prior knowledge of what kind of words or phonemes are likely to be observed.
 - P(w|o): conditional probability of word observation, given acoustic observation of o.
 - (specific) o --> w1, w2, w3, ...? o --> p1, p2, p3, ...?
 - Data collection is very difficult to characterize or formulate P(w|o) directly.
- Use of the Bayesian rule

$$P(w|o) = rac{P(w,o)}{P(o)} = rac{P(o|w)P(w)}{\sum_w P(o,w)} = rac{P(o|w)P(w)}{\sum_w P(o|w)P(w)}$$

- The denominator is independent of w.
- Maximization of P(w|o) in terms of w is equal to that of P(o|w)P(w) (=P(o,w))
- Solution of argmax_{w} P(o|w) P(w)
 - P(w): can be estimated from a large text corpus.
 - P(o|w): conditional probability of acoustic observation, given intended content of w.
 - (specific) w --> o1, o2, o3, ...? p --> o1, o2, o3, ...?
 - This data collection is possible enough by asking many speakers to say w or p!!
 - P(o|w): acoustic model, P(w): linguistic model
 - Separate two models and a program that can search for the word sequence that maximizes P(o,w)

Cognitive Media Processing @ 2015

Waveforms --> spectrums --> sequence of feature vectors

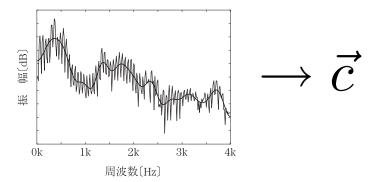

$$\arg \max_{w} P(w_1, w_2, ..., w_N | o_1, ..., o_t, ..., o_T) =$$

$$\arg \max_{w} P(o_1, ..., o_t, ..., o_T | w_1, w_2, ..., w_N) P(w_1, w_2, ..., w_N)$$

o: cepstrum vector

Cep. distortion and DTW

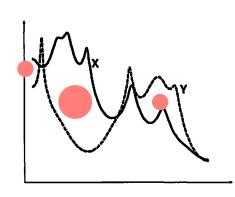

Cepstrum vector = spectrum envelope

- 2 cepstrum vectors always satisfy the following equation.
 - log|Sn|, log|Tn|: 2 spectrums
 - log|S'n|, log|T'n|: 2 spectrum envelopes that are characterized by M cepstrums.
 - Euclid distance of cepstrums has a clear physical meaning.

$$D_n = \left(\log|S'_n| - \overline{\log|S_n|}\right) - \left(\log|T'_n| - \overline{\log|T_n|}\right)$$

$$2\sum_{k=1}^{M} (c_k^S - c_k^T)^2 = \frac{1}{N} \sum_{i=0}^{N-1} D_n^2$$

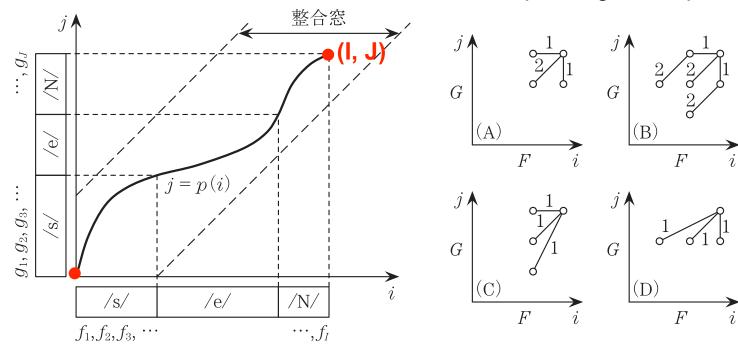

Cep. distortion and DTW

- Dynamic Time Warping
 - Temporal alignment between two utterances of the same content
 - Temporal alignment between two utterances of different contents
 - Finding the best path that minimizes the accumulated distortion along that path.

$$\min_{p} \left[\frac{1}{Z} \sum_{i=1}^{I} d(f_i, g_{p(i)}) \right]$$

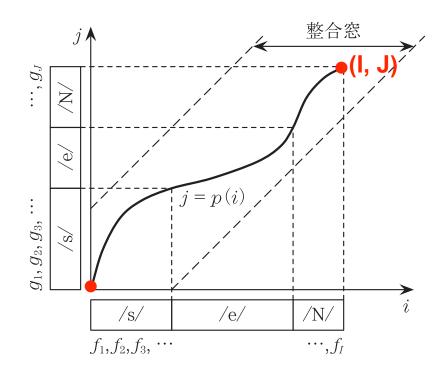

• Local distortion: $d(f_i, g_j)$ = Euclid distance of the corresponding two cepstrum vectors.

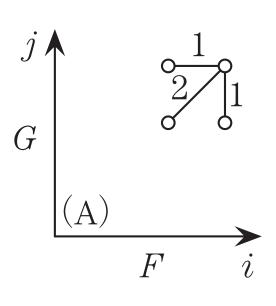

Cep. distortion and DTW

- Total distortion accumulated up to point (i,j) = D(i,j)
 - d(i,j) = local distortion (distance) between fi and gj.

$$D(i,j) = \min \begin{bmatrix} D(i,j-1) + d(i,j) \\ D(i-1,j-1) + 2d(i,j) \\ D(i-1,j) + d(i,j) \end{bmatrix} \longrightarrow \min_{p} \left[\frac{1}{Z} \sum_{j} d(i,p(i)) \right] = \frac{1}{I+J-1} D(I,J)$$

 - This data collection is possible enough by asking many speakers to say w or p!!
 - P(o|w): acoustic model, P(w): linguistic model
 - Separate two models and a program that can search for the word sequence that maximizes P(o,w)

Markov Process

$$P(x_n|x_{n-1},\dots,x_1) = P(x_n|x_{n-1})$$

- Signal at t = n depends only on the previous signal (t=n-1).
- If signal at t = n-1 is known, signals at t < n-1 have no effect on the next signal at t = n.

Hidden Markov Process

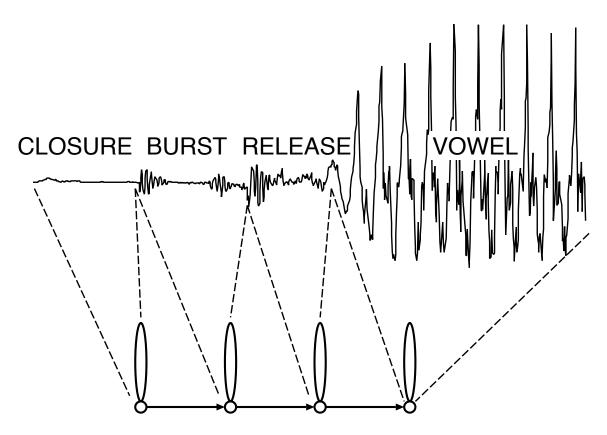

$$P(x_n | \underbrace{x_{n-1}, \cdots, x_1}) = P(x_n | \underbrace{S_n})$$
 previous observations

Observation sequence : $x_1, x_2, \dots, x_n, \dots$ (Hidden) state sequence : $S_1, S_2, \dots, S_n, \dots$

- Previous observations cannot determine the current state uniquely.
- Signals (features) are observed but states are hidden.

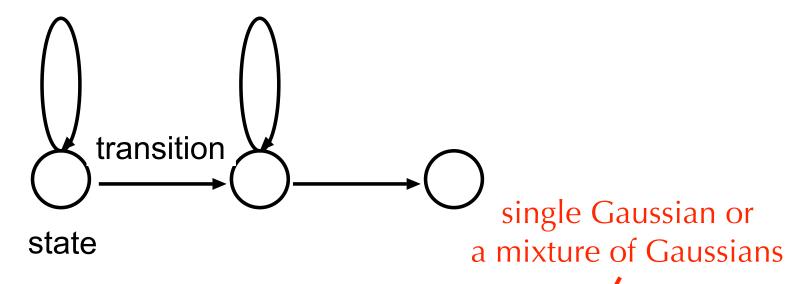

HMM as generative model

Probabilistic generative model

State transition is modeled as transition probability. Output features are modeled as output probability.

Parameters of HMM

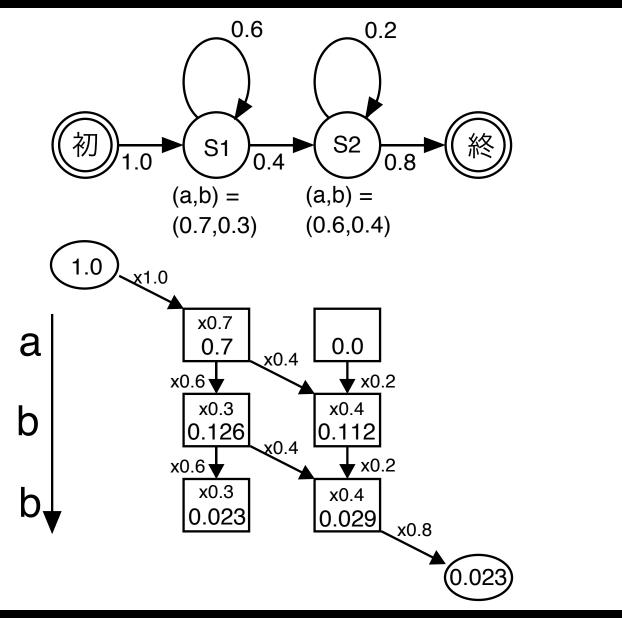

- Transition prob. : $P(s_{t+1}|s_t=i)=\{a_{1i},a_{2i},...,a_{ji},...,a_{Si}\}$ Output prob. : $P(o|s_t=i)=b_i(o)=\mathcal{N}(o;\mu_i,\Sigma_i)$
- Forward prob.

$$\alpha_j(t) = P(o_1, \dots, o_t, s(t) = j|M) \qquad = \sum_i \alpha_i(t-1)a_{ij}b_j(o_t)$$

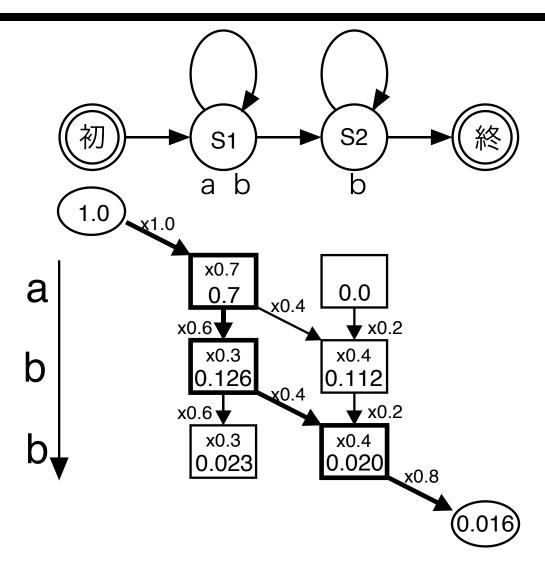

Backward prob.

$$eta_j(t) = P(o_{t+1}, \cdots, o_T | s(t) = j, M) = \sum_i a_{ji} b_i(o_{t+1}) eta_i(t+1)$$

Output probability of observation sequence (Trellis)

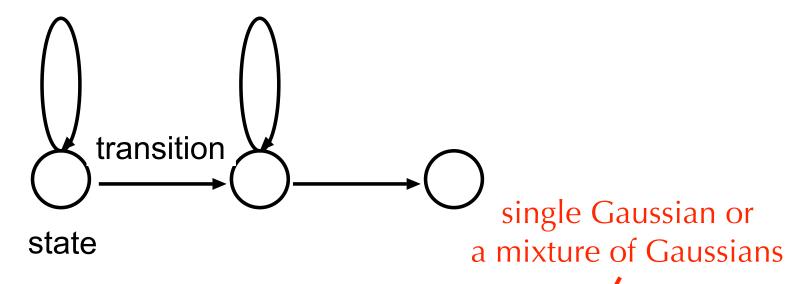

Output probability of observation sequence (Viterbi)

The maximum likelihood path is only adopted.

Parameters of HMM

- Transition prob. : $P(s_{t+1}|s_t=i)=\{a_{1i},a_{2i},...,a_{ji},...,a_{Si}\}$ Output prob. : $P(o|s_t=i)=b_i(o)=\mathcal{N}(o;\mu_i,\Sigma_i)$
- Forward prob.

$$\alpha_j(t) = P(o_1, \dots, o_t, s(t) = j|M) \qquad = \sum_i \alpha_i(t-1)a_{ij}b_j(o_t)$$

Backward prob.

$$eta_j(t) = P(o_{t+1}, \cdots, o_T | s(t) = j, M) = \sum_i a_{ji} b_i(o_{t+1}) eta_i(t+1)$$

Estimation is done iteratively by updating old parameters.

Forward prob.

$$\alpha_j(t) = P(o_1, \dots, o_t, s(t) = j|M)$$

$$= \sum_i \alpha_i(t-1)a_{ij}b_j(o_t)$$

Backward prob.

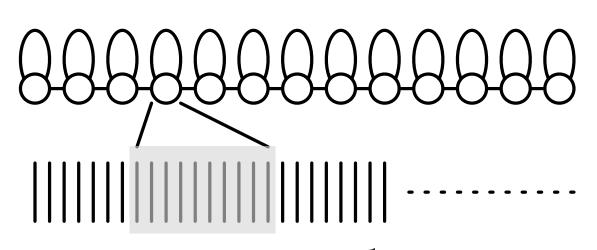

$$\beta_j(t) = P(o_{t+1}, \dots, o_T | s(t) = j, M) = \sum_i a_{ji} b_i(o_{t+1}) \beta_i(t+1)$$

$$\rightarrow \alpha_j(t)\beta_j(t) = P(O, s(t) = j|M)$$

$$\rightarrow P(s(t) = j|O, M) = \frac{\alpha_j(t)\beta_j(t)}{P(O|M)} = \frac{\alpha_j(t)\beta_j(t)}{\alpha_N(T)} = L_j(t)$$

→ Represents how strongly ot is associated with state j.

$$\rightarrow \hat{\mu}_{j} = \frac{\sum_{t}^{\Sigma} L_{j}(t) \cdot o_{t}}{\sum_{t}^{\Sigma} L_{j}(t)} = \frac{\sum_{t}^{\Sigma} \alpha_{j}(t) \beta_{j}(t) \cdot o_{t}}{\sum_{t}^{\Sigma} \alpha_{j}(t) \beta_{j}(t)} \qquad P(O|\hat{M}) \ge P(O|M)$$

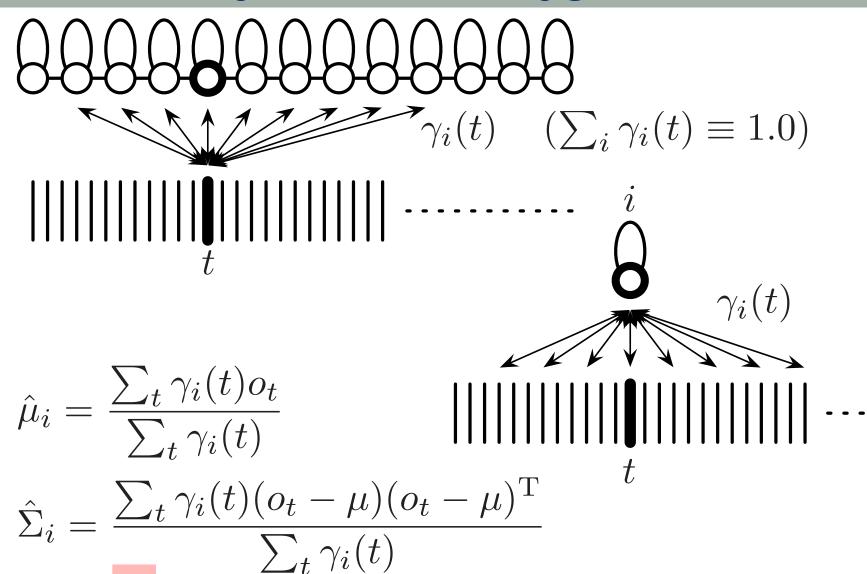

$$\mu = \frac{1}{T} \sum_{t} o_{t} = \frac{\sum_{t} \frac{1}{T} o_{t}}{\sum_{t} \frac{1}{T}}$$

$$1 \sum_{t} o_{t} = \sum_{t} o_{t} = \sum_{t} o_{t}$$

$$\Sigma = \frac{1}{T} \sum_{t}^{t} (o_t - \mu)(o_t - \mu)^{\mathrm{T}}$$

Cognitive Media Processing @ 2015

$$P(O|\hat{M}) \ge P(O|M)$$

Estimation is done iteratively by updating old parameters.

Forward prob.

$$\alpha_j(t) = P(o_1, \dots, o_t, s(t) = j|M)$$

$$= \sum_i \alpha_i(t-1)a_{ij}b_j(o_t)$$

Backward prob.

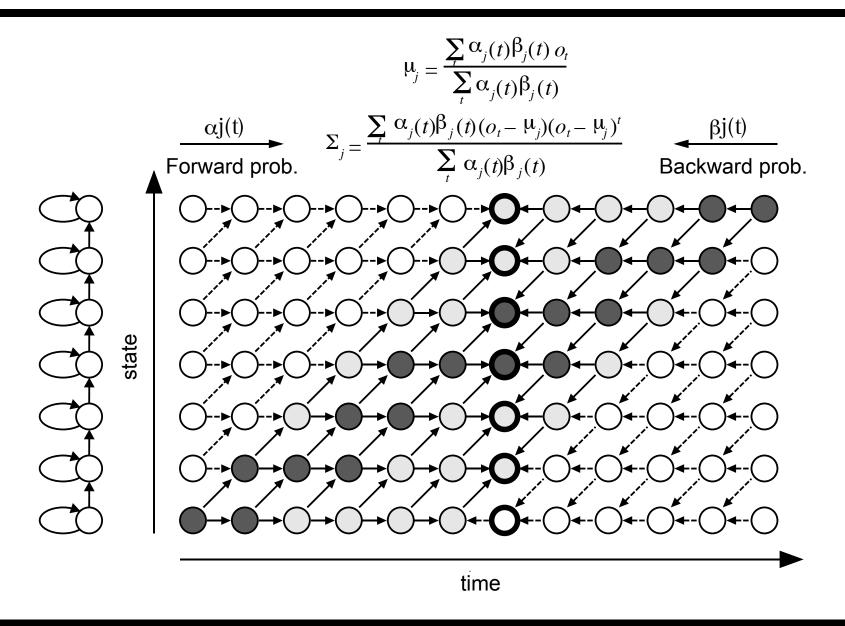

$$\beta_j(t) = P(o_{t+1}, \dots, o_T | s(t) = j, M) = \sum_i a_{ji} b_i(o_{t+1}) \beta_i(t+1)$$

$$\rightarrow \alpha_j(t)\beta_j(t) = P(O, s(t) = j|M)$$

$$\rightarrow P(s(t) = j|O, M) = \frac{\alpha_j(t)\beta_j(t)}{P(O|M)} = \frac{\alpha_j(t)\beta_j(t)}{\alpha_N(T)} = L_j(t)$$

→ Represents how strongly ot is associated with state j.

$$\rightarrow \hat{\mu}_{j} = \frac{\sum_{t}^{\Sigma} L_{j}(t) \cdot o_{t}}{\sum_{t}^{\Sigma} L_{j}(t)} = \frac{\sum_{t}^{\Sigma} \alpha_{j}(t) \beta_{j}(t) \cdot o_{t}}{\sum_{t}^{\Sigma} \alpha_{j}(t) \beta_{j}(t)} \qquad P(O|\hat{M}) \ge P(O|M)$$

• When the number of training data is 1,

$$\hat{\mu}_j = \frac{\sum_{t=1}^{T} L_j(t) \cdot o_t}{\sum_{t=1}^{T} L_j(t)}, \quad \hat{\Sigma}_j = \frac{\sum_{t=1}^{T} L_j(t) \cdot (o_t - \mu_j)(o_t - \mu_j)^t}{\sum_{t=1}^{T} L_j(t)}$$

When the number of training data is R (>1),

$$\hat{\mu}_{j} = \frac{\sum\limits_{r} \left[\sum\limits_{t} L_{j}^{r}(t) \cdot o_{t}^{r}\right]}{\sum\limits_{r} \left[\sum\limits_{t} L_{j}^{r}(t)\right]} = \frac{\sum\limits_{r} \frac{1}{P^{r}} \left[\sum\limits_{t} \alpha_{j}^{r}(t) \beta_{j}^{r}(t) \cdot o_{t}^{r}\right]}{\sum\limits_{r} \frac{1}{P^{r}} \left[\sum\limits_{t} \alpha_{j}^{r}(t) \beta_{j}^{r}(t)\right]}$$

$$\hat{\Sigma}_{j} = \frac{\sum_{t} \left[\sum_{t} L_{j}^{r}(t) \cdot (o_{t}^{r} - \mu_{j})(o_{t}^{r} - \mu_{j})^{t} \right]}{\sum_{t} \left[\sum_{t} L_{j}^{r}(t) \right]} = \cdots$$

#speakers = several thousands

Recognition of isolated words

 $\arg\max_{W} P(W|O) = \arg\max_{W} P(O|W)P(W) = \arg\max_{W} P(O|W)$

if prior probability of W is evenly distributed.

$$\arg \max_{M} P(O|M) = \arg \max_{M} \left\{ \sum_{X} P(O, X|M) \right\}$$

$$\downarrow \qquad (X = \mathsf{path})$$

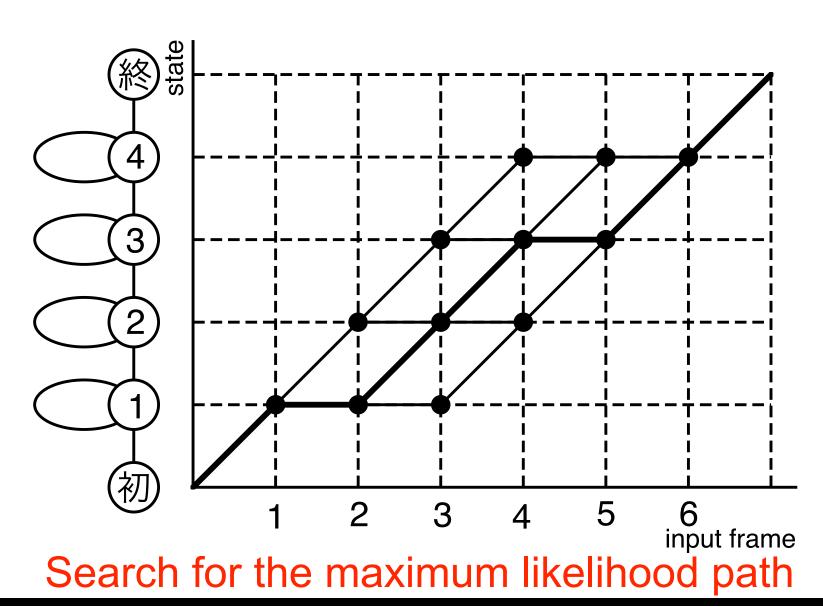

$$\arg \max_{M} \hat{P}(O|M) = \arg \max_{M} \left\{ \max_{X} P(O, X|M) \right\}$$

$$\alpha_{j}(t) = \sum_{i} \alpha_{i}(t-1)a_{ij}b_{j}(o_{t}), \quad (\alpha_{N}(T) \equiv P(O|M))$$

$$\downarrow$$

$$\phi_{j}(t) = \max_{i} \phi_{i}(t-1)a_{ij}b_{j}(o_{t}), \quad (\phi_{N}(T) \equiv \hat{P}(O|M))$$

Recognition of isolated words

| 課長 | k a ch o: |
| の | n o |
| お願いします | onegaishimasu |

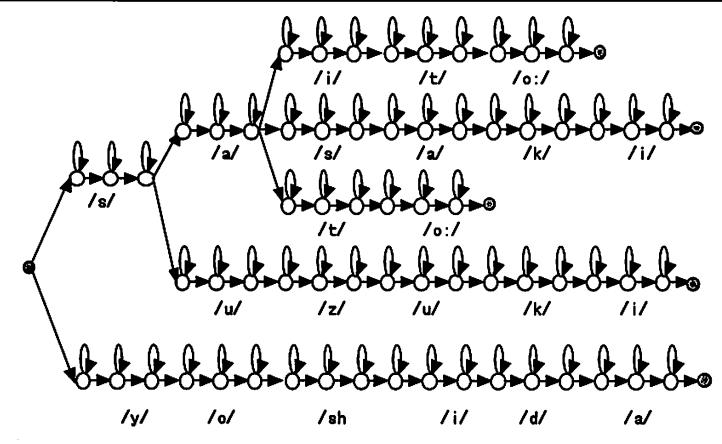

Tree lexicon (compact representation of the words)

The following words saito: (斉腐 are stored as a tree.

saito: (斉藤), sasaki (佐々木), sato: (佐藤) suzuki (鈴木), yoshida (吉田)

Tree-based lexicon using phoneme HMMs

Generation of state-based network containing all the candidate words

Coarticulation and context-dependent phone models

Acoustic features of a specific kind of phone depends on its phonemic context.

model of
$$/k/$$

$$= *-k+* = a-k+a a-k+u a-k+o \dots$$

$$= -k+o i-k+o$$

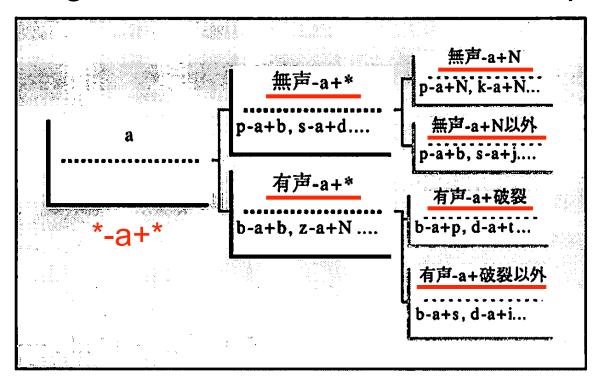

$$= -k+o i-k+o$$

model of /k/
preceded by /a/ and = a-k+i
succeeded by /i/ trihphone

A phoneme is defined by referring to the left and the right context (phoneme)

Clustering of phonemic contexts

Number of logically defined trihphones = N x N x N (N \approx 40) Clustering of the contexts to reduce #triphones.

Context clustering is done based on phonetic attributes of the left and the right phonemes.

Unit of acoustic modeling

| | merit: | Within-word coarticulation effect is easy to model. |
|------------------|----------|--|
| word model | demerit: | For new words, actual utterances are needed. #models will be easily increased. |
| | use: | Small vocabulary speech recognition systems |
| | merit: | Easy to add new words to the system. |
| | illelit. | Lasy to add fiew words to the system. |
| phoneme model | demerit: | Long coarticulation effect is ignored. Every word has to be represented as phonemic string. |

GMM-HMM to DNN-HMM

GMM-HMM

DNN-HMM (ハイブリッド)

- How to obtain the HMM state for each frame in the training data?
 - DNN-HMM trains GMM-HMM internally at first.
 - (Forced) alignment between GMM-HMM and training data is done.
 - Then, the state for each frame is fixed and labeled.

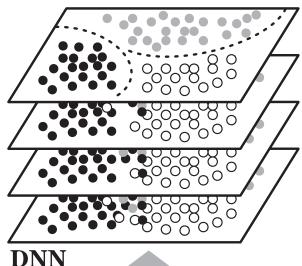

Why GMM-HMM < DNN-HMM?

- GMM = Generative model, DNN = Discriminative model
 - Generative model has to characterize the probability distribution of manuallycrafted features such as cepstrum coefficients, given classes (= P(o | c))
 - Discriminative model has to characterize the probability distribution of classes, given acoustic observations (= P(c | o))
 - o → linear transform + non-linear normalization → o'
 - o' → linear transform + non-linear normalization → o"

 Multiple "feature" transformations are trained (designed) so that better features are "automatically" created for classification.

- 営業の佐藤さんお願いします。
- 営業の鈴木さんお願いします。

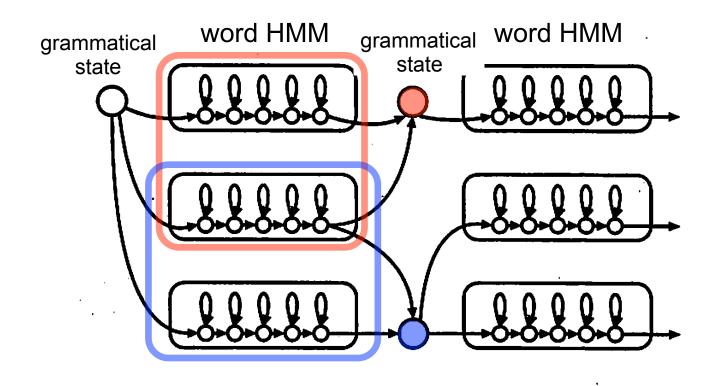

Network grammar with a finite set of states

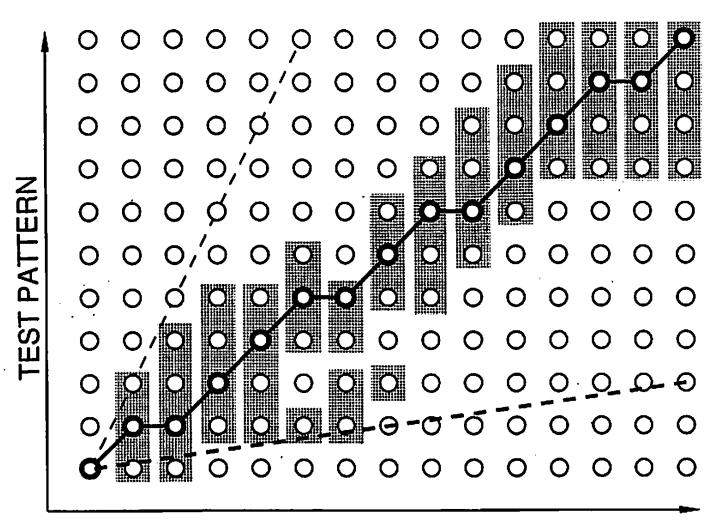

A sentence is accepted if it starts at one of the initial states and ends at one of the final states.

Speech recognition using a network grammar

When a grammatical state has more than one preceding words, the word of the maximum probability (or words with higher probabilities) is adopted and it will be connected to the following candidate words.

Viterbi search algorithm

Probabilities of P(OO|A) and P(OO|B)

袋A:
$$\frac{3}{10} \times \frac{7}{10} \times \frac{3}{10} = 0.063$$
 袋B: $\frac{7}{10} \times \frac{3}{10} \times \frac{7}{10} = 0.147$

Decision: The bag used is more likely to be B.

Statistical framework of speech recognition

$$P(W|A) = \frac{P(A,W)}{P(A)} = \frac{P(A|W)P(W)}{P(A)} = \frac{P(A|W)P(W)}{\sum_{W} P(A|W)P(W)}$$
A = Acoustic, W = Word

- $P(bag| \bullet \bigcirc \bullet) \longrightarrow P(bag=A| \bullet \bigcirc \bullet)$ or $P(bag=B| \bullet \bigcirc \bullet)$
- P(●○●|bag=A): prob. of bag A's generating ●○●.
- P(bag) --> P(bag=A) or P(bag=B) Which bag is easier to be selected?

If we have three bags of type-A and one bag of type-B, then

$$P($$
袋A | •••) = $0.063 \times 0.75 = 0.04725$
 $P($ 袋B | •••) = $0.147 \times 0.25 = 0.03675$

The bag used is likely to be A.

N-gram language model

The most widely-used implementation of P(w)

Only the previous N-1 words are used to predict the following word. (N-1)-order Markov process

$$P(x_1, \dots, x_n) = \underbrace{P(x_n | \underline{x_1, \dots, x_{n-1}})}_{\approx P(x_n | \underline{x_{n-N+1}, \dots, x_{n-1}})} P(x_1, \dots, x_{n-1})$$

$$\approx P(x_n | \underline{x_{n-N+1}, \dots, x_{n-1}}) P(x_1, \dots, x_{n-1})$$

$$\approx \prod_{i=1}^{n} P(x_i | x_{n-N+1}, \dots, x_{i-1})$$

I'm giving a lecture on speech recognition technology to university students.

P(a | I'm, giving), P(lecture | giving, a), P(on | a, lecture), P(speech | lecture, on), P(recognition | on, speech), ...

How to calculate N-gram prob.

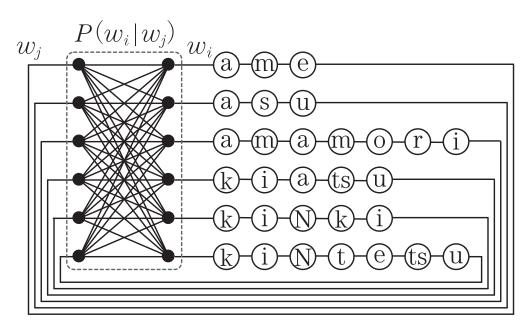

```
.... lecture on speech recognition ....
 P(speech | lecture, on)
     = C (lecture, on, speech) / C (lecture, on)
 P(recognition | on, speech)
     = C (on, speech, recognition) / C (on, speech)
 P(w3 | w1, w2)
     = C (w1, w2, w3) / C (w1, w2)

    Typical problems of calculating N-gram prob

 C(w1, w2, w3) = 0 --> N-gram prob. = 0
 C(w1, w2) = 0 --> N-gram prob. = ???
 \alpha \times P(w3 \mid w1) or \beta \times P(w3) are substituted as P(w3 | w1, w2).
  Context dependencies are ignored to some degree.
```

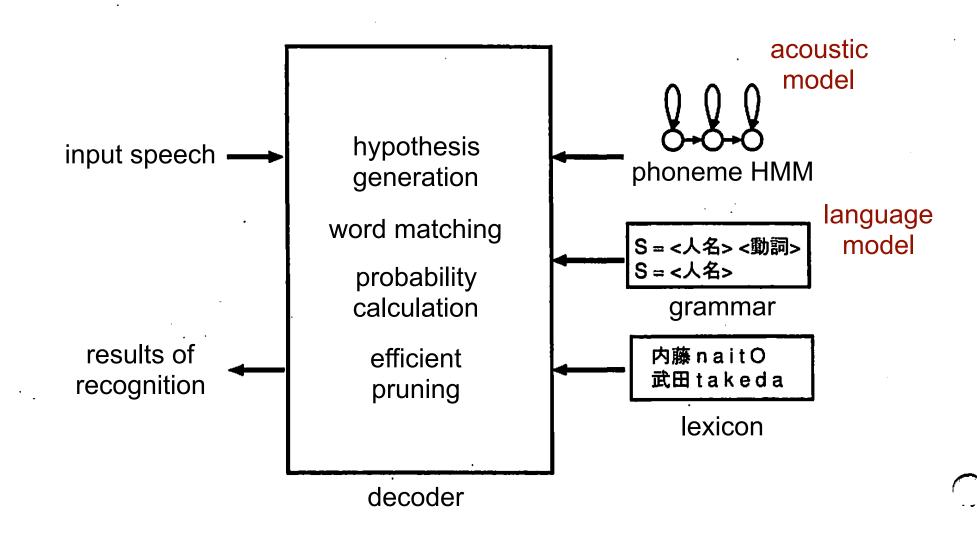

2-gram as network grammar

2-gram as network grammar and as tree-based network grammar
